

MAN TEST 1

Test reference no. 12

This test involves the user completing the following steps:

- Opening and loading up the game.
- Click each button individually.

The test will be considered successful if the UI visually responds as expected, and does so within an appropriate time frame (no/minimal lag). The test will otherwise be considered to have failed.

This must be a manual test rather than automated as it requires human judgement of the UI graphics altering appropriately, which cannot be measured via unit test.

- What part of the project is being tested?

All UI button options.

- Which property is being tested?

Correctness, responsiveness and consistency.

- Why these specific tests? (design techniques..)

These tests ensure the UI responds as intended, focusing on identifying visual inconsistencies.

- When will it be tested?

Upon each major release and all minor releases with UI element alterations.

- Where are we testing it?

On at least 1 sample machine across each platform (windows, macOS, etc)

- Who will execute the test and analyse the results?

A designated representative of the testing team.

MAN TEST 2

Test reference no. 13

This test involves the user completing the following steps:

- Opening the game, and remaining in the main menu.
- Click on the settings option, and alter the volume of the game.
- Exit the settings menu, and open the leaderboard.
- Exit the leaderboard, and open the achievements.
- Exit the achievements screen, resize the window.
- Click the play button and once again alter the window size whilst not in the tutorial or pause menu (active game).

The test will pass if they are able to complete all of the above actions, and believe that the UI graphics visually responded in an appropriate manner. Eg: altering the scale of important UI elements depending on window size, displaying the correct information, etc.

This must be a manual test rather than automated as it requires human judgement of the UI graphics altering appropriately, which cannot be measured via unit test.

- What part of the project is being tested?

The options on the main menu screen and screen resizability.

- Which property is being tested?

Consistency and usability.

- Why these specific tests?

This test ensures that the main menu UI and screen resizing feature respond to interaction in a visually appropriate manner.

- When will it be tested?

Upon each major release and all minor releases with UI element alterations.

- Where are we testing it?

On at least 1 sample machine across each platform (windows, macOS, etc)

- Who will execute the test and analyse the results?

A designated representative of the testing team.

MAN TEST 3

Test reference no. 14

This test involves the user completing the following steps:

- Opening the game and loading it up via the play button until the enable/disable tutorial screen appears.
- Opening a stopwatch on another device.
- Starting the stopwatch as the disable tutorial button is clicked.
- Pausing the stopwatch upon the duck death, and verifying that it does in fact occur at 3 minutes in (minus 2 seconds for the time taken for the tutorial to show).

The test will pass if no inconsistencies are noted between the ingame timer and the stopwatch. If any are noted, for example, the in game timer seems to be marginally slower/faster than the stopwatch, then the test fails.

This must be a manual test rather than automated as it requires cross-referencing of the timers on two different devices, without any lag/delay that would be invoked by referencing the time via an automated test. It also requires human judgement, as the game is only 5 minutes, if there was an extremely small delay an automated test would perhaps flag it but, if it would not be noticeable to a human within the 5 minutes of playtime, that would be considered a false fail.

- What part of the project is being tested?

The in game 5 minute timer.

- Which property is being tested?

Consistency, correctness and accuracy.

- Why these specific tests?

It ensures that the timer does in fact run for 5 minutes, as discrepancies between this and real world minutes would invoke confusion and harm learnability and adaptability of the system.

- When will it be tested?

Upon each major release and all minor releases with UI element alterations.

- Where are we testing it?

On at least 1 sample machine across each platform (windows, macOS, etc)

- Who will execute the test and analyse the results?

A designated representative of the testing team.

MAN TEST 4

Test reference no. 15

This test involves the user completing the following steps:

- Opening and loading up the game.
- Waiting for the tutorial enable/disable screen to show.
- Selecting enable tutorial.
- Closing the game and repeating the above steps, selecting the disable tutorial option instead.

The test will pass if the `println` statement correctly returns the options that the user has picked, and will fail otherwise.

This must be a manual test rather than automated as it is checking that the UI on the buttons is appropriate for their functionality, requiring human judgement to confirm that the UI displays as intended.

- What part of the project is being tested?

The tutorial UI.

- Which property is being tested?

Usability and readability.

- Why these specific tests?

It ensures that there are no discrepancies between what buttons imply they do and what they actually do, as if there were any, it would invoke confusion in users and negatively affect the learnability and usability of the system.

- When will it be tested?

Upon each major release and all minor releases with UI element alterations.

- Where are we testing it?

On at least 1 sample machine across each platform (windows, macOS, etc)

- Who will execute the test and analyse the results?

A designated representative of the testing team.
